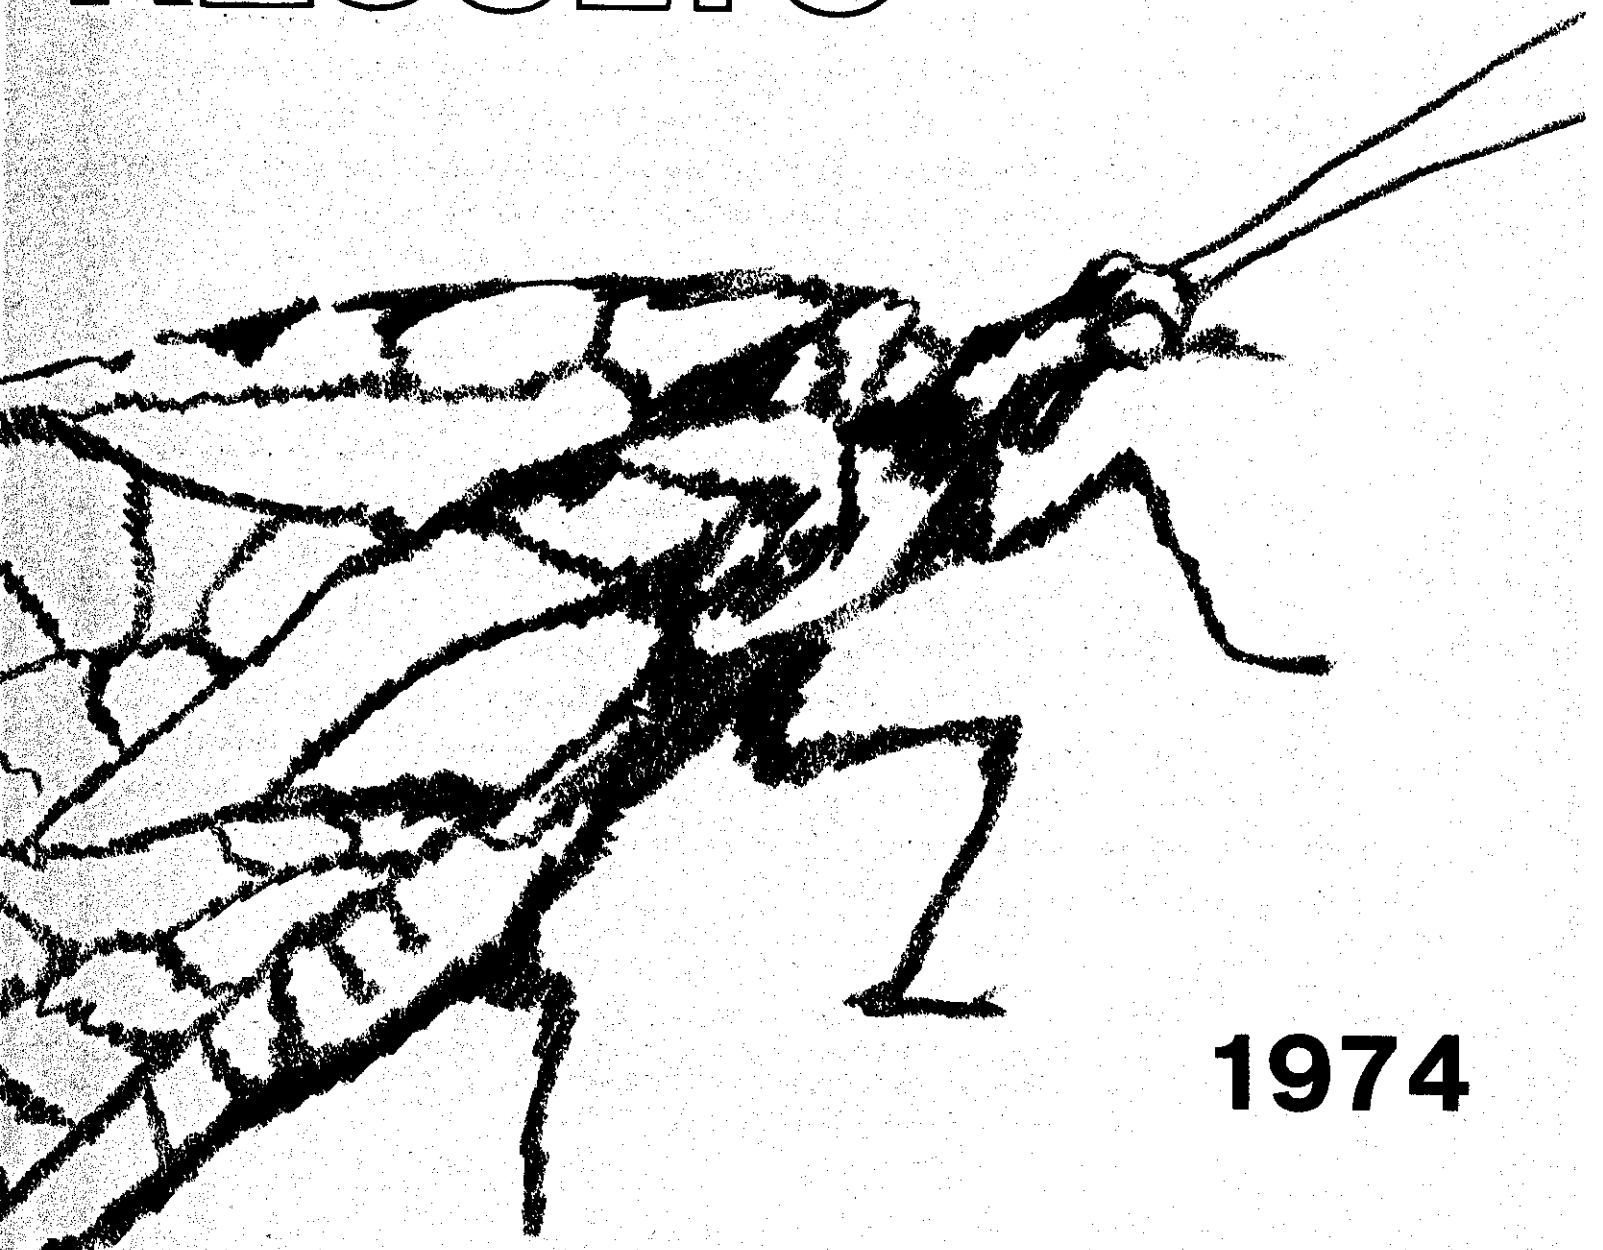
A PROGRESS REPORT OF

Sharon C. Mueller

INSECT STUDY RESULTS



1974

IN SEED ALFALFA

Acknowledgements

The work reported here was made possible by the financial support of seed growers and seed processors through the Alfalfa Seed Production Research Board. This support and cooperation and that received from chemical companies is greatly appreciated.

The assistance of grower cooperators and chemical applicators who donated their time, equipment and fields to conduct these experiments is also deeply appreciated. Special thanks are due Don Darnell of Panoche Chemical Company, Bob Vance of Tri-air, Wilbur Ellis Company and John Mallyon, James Irrigation District for their interest and many hours of work with these and past experiments concerning insect control in seed alfalfa.

Experiments were conducted in alfalfa seed fields of the following growers: John Maitia, Paul and Roland Crevolin, John Nakamura and in an 18 acre untreated seed field maintained by Don Darnell on land provided by Telles Ranch Incorporated. It was necessary in certain experimental areas to allow insect populations to remain untreated or to reach higher than recommended levels in order to obtain desired information on population trends or control effectiveness of pesticides. In doing so, growers may have experienced some losses in seed quality and quantity in certain of the experimental plots. We are grateful for their interest and these contributions in making it possible to conduct the experiments. The assistance of students, Ben Simko and Jon Knapp in carrying out the various surveys and experiments and the art work of Carolyn Oda, Agricultural Extension Service, Fresno, is sincerely appreciated.

Research on Insects Affecting Seed Alfalfa 1974

O. G. Bacon[1], B. Sheesley[2], W. D. Riley[3] and R. H. James[3]

Introduction

This progress report summarizes research on insects affecting seed alfalfa conducted during 1974. It is our desire to fully inform seed growers, processors and agribusiness cooperators of the research conducted with their generous and much appreciated support.

The contents of this summary should not be interpreted as recommendations of the University of California. Insect control recommendations are published by the University of California and can be obtained free of charge from the Farm and Home Advisors Office.

Common and/or manufacturer's names of insecticides are used in this report instead of the less familiar chemical terms, but no endorsement of products mentioned is intended. The rates of insecticides applied per acre are all expressed as active material per treated acre. Some of the chemicals included in the experiments reported are not registered for commercial use on seed alfalfa at this time.

The common and/or manufacturer's names of insecticides mentioned in this report are as follows:

Bay Hox 1901	SD8832 10G
Carzol®	Temik 10G®
dimethoate	TEPP
Lannate®	Thiodan®
Lorsban®	UniRoyal K840
Monitor®	Vydate®

[1] Entomologist, Department of Entomology, University of California, Davis.

[2] Farm Advisor, Fresno County.

[3] Staff Research Associates, Department of Entomology, University of California, Davis.

These experiments were conducted in the San Joaquin Valley where the honeybee is the principal pollinator. We have no information concerning the effects of these insecticides and programs on leafcutting or alkali bees.

Discussion of 1974 Research Results

Research was continued on the control of lygus bugs, aphids and spider mites and on the biology and population dynamics of the consperse stink bug and other insects affecting seed alfalfa. During 1974, five separate experiments were conducted in which twelve insecticides and seven insecticide combinations were evaluated for control of lygus bugs and the spotted alfalfa aphid. Detailed biological studies were conducted in several commercial alfalfa seed fields and in a field specifically maintained for insect population studies. Although data were obtained on several insect species in each of the individual experiments, the results are categorized and reported according to species rather than by individual experiment.

Lygus bugs

Seven insecticides and seven insecticide combinations were evaluated for control of lygus bugs in five separate experiments. The insecticides and combinations applied as foliar sprays by aircraft were Bay Hox 1901, dimethoate, Lorsban®, Monitor®, Vydate®, Carzol® + Thiodan®, Carzol + UniRoyal K840, Carzol + Lorsban, Carzol + Lannate, Carzol + TEPP, Carzol + Vydate and Lannate® + TEPP. Temik® and SD8832 were applied to the soil as granular formulations with a commercial soil applicator. The following briefly summarizes the results obtained with each of the materials in controlling lygus bugs.

Bay Hox 1901, an experimental compound of Chemagro Corporation, applied at 0.5 lb. active ingredient per acre resulted in an initial reduction of the lygus bug population of 70 per cent over pretreatment counts but the material appeared to have a short residual toxicity, populations reached pretreatment levels within 13 days after application. Dimethoate, a long used standard, applied at 0.5 lb. AI/A reduced the lygus bug population approximately 97 per cent under the pretreatment level and and the population did not attain the pretreatment level for 20 days after application. Lorsban (formerly Dursban) was evaluated in two experiments

at 0.5 and 1.0 lb. AI/A and with and without a buffering agent (Buffer-X). Lygus bug control was not consistent. In an experiment conducted in June, Lorsban at 1.0 lb. AI/A with and without Buffer-X resulted in almost total initial control of lygus bugs. The addition of Buffer-X did not alter the control over that obtained with the Lorsban alone. Approximately 20 days elpased before lygus populations returned to pretreatment levels in both plots. A second application of Lorsban without buffer applied to the same plot was not as effective as the first, this time the population was reduced approximately 39 per cent over the pretreatment level. Within 13 days after this application the lygus bug population was almost double that at pretreatment.

In a later experiment Lorsban was evaluated at two rates, 0.5 and 1.0 lb. AI/A. Very low lygus bug populations were present at the time of treatment but 13 days after application populations were 10 to 20 times greater than the pretreatment levels. The 1.0 lb. rate was more effective than the 0.5 lb. rate in reducing lygus bug populations but neither rate provided adequate control. It would seem that Lorsban has a short residual toxicity for lygus bugs.

Monitor applied at 0.5 lb. AI/A resulted in an initial lygus bug population reduction of 98 per cent under the pretreatment level and 27 days after application the population, although increasing, was 44 per cent below the pretreatment level. A second application of Monitor at the same rate to the same plot also effectively controlled lygus bugs but this experiment was terminated 13 days after the second application because of heavy spotted alfalfa aphid populations.

Vydate applied at 0.75 lb. AI/A resulted in an initial reduction in the lygus bug population of 98 to 100 per cent. This material appeared to have a long residual toxicity for lygus bugs. Thirty-four days elapsed before lygus bug populations exceeded the pretreatment level. Vydate applied at 0.5 lb. AI/A in a second experiment also gave excellent control of lygus bugs but it was necessary to terminate this experiment 13 days after application because of extremely large spotted alfalfa aphid populations.

Past experiments have shown that where Carzol has been used alone on alfalfa varieties susceptible to the spotted alfalfa aphid, these applications have resulted in serious spotted alfalfa aphid infestations. For this reason, Carzol was combined in 1974, with other insecticides that might effectively control the aphid populations.

The following insecticides were tested in combination with Carzol 0.5 lb. AI/A: Thiodan 1.0 lb. AI/A, UniRoyal K840 0.5 lb. AI/A, Lorsban 1.0 lb. AI/A, Lannate 0.75 lb. AI/A, TEPP 1.0 lb. AI/A, and Vydate 0.75 lb. AI/A. Combinations of Carzol 0.75 lb. AI/A plus UniRoyal K840 0.5 lb. AI/A and Lannate 0.75 lb. AI/A plus TEPP 1.0 lb. AI/A were also evaluated. The Carzol-Thiodan combination was used as a standard treatment in four experiments. With one exception, this combination gave excellent control of lygus bugs. Initial population reductions of 95 to 97 per cent under pretreatment levels were obtained and populations did not reach pretreatment levels for 20 to 27 days after application. The one failure with this combination is believed to have been the result of poor timing with respect to a large egg population and subsequent hatch. As will be shown later in this report, Thiodan did not control the spotted alfalfa aphid.

Carzol plus UniRoyal K840 resulted in good control of lygus bugs but did not reduce nymph populations as well as the Carzol-Thiodan combination. UniRoyal K840 is a specific aphicide having virtually no effect on other insects. Thiodan, however, appeared to contribute to the total toxicity of the combination for lygus bugs.

Combinations of Carzol with Lorsban, Lannate and TEPP all effectively controlled lygus bugs for periods of 13 days. The Carzol-Vydate combination was highly effective in controlling lygus bugs but appeared to be no better than Vydate alone at 0.5 or 0.75 lb. AI/A.

A Lannate-TEPP combination was used in two experiments late in the season, on August 21 and 28. This combination resulted in excellent control of lygus bugs but it was not possible to follow the treatments for more than 13 days after application.

An experiment was conducted to evaluate timing and repeated applications throughout the season of Carzol 0.5 lb. AI/A + Thiodan 1.0 lb. AI/A and Carzol 0.75 lb. AI/A + UniRoyal K840 0.5 lb. AI/A for lygus bug control. The Carzol-Thiodan combination was applied to two 10 acre plots and the Carzol UniRoyal K840 combination was applied to a 5 acre plot. After the initial treatment of all three plots on June 12, one of the Carzol-Thiodan plots was retreated when total lygus bug counts (adults + nymphs) reached 4 to 6 bugs per sweep. The other two plots, Carzol-Thiodan and Carzol-UniRoyal K840 were retreated when counts reached 8 to 12 bugs per sweep. The alfalfa variety was Altfranken Schmidt, susceptible to the spotted

alfalfa aphid. It was apparent after the second applications of Carzol-Thiodan on July 10 and 17 that the spotted alfalfa aphid was not being controlled. TEPP 1.0 lb. AI/A was applied to both Carzol-Thiodan plots on July 24 but did not control the aphid. On August 7, Lorsban 0.5 and 1.0 lb. AI/A was applied to the 4 to 6 bug/sweep Carzol-Thiodan plot and Lannate 0.75 + TEPP 1.0 lb. AI/A was applied to the 8 to 12 bug/sweep Carzol-Thiodan plot. These insecticides resulted in excellent aphid control and Lannate-TEPP was used for the final application in both of the original Carzol-Thiodan plots. It was not necessary to add an aphicide treatment to the Carzol-UniRoyal K840 plot, for the K840 provided excellent control of the spotted alfalfa aphid. The plots treated at counts of 8 to 12 bugs per sweep received three applications for lygus bug control during the season ranging from 20 to 34 days apart. The plot treated at counts of 4 to 6 bugs per sweep received a total of four insecticide applications for lygus bug control ranging from 20 to 27 days apart.

At harvest, four one-quart samples of seed pods were hand stripped from each plot. Samples were hand threshed and lightly cleaned in a Clipper seed cleaner. The seeds were examined for lygus bug injury, seed chalcid, stink bug and other damage. The per cent of good seeds in the Carzol-Thiodan plots treated at counts of 4 to 6 bugs per sweep and at 8 to 12 bugs per sweep was 96.3 and 95.6 respectively. Seeds showing lygus bug injury in the two plots represented 1.9% and 2.3% respectively of the total seeds examined in each. The per cent of good seeds from the plot treated with Carzol-UniRoyal K840 at counts of 8 to 12 bugs per sweep was 93.6 and the per cent showing lygus bug injury was 3.3. The center 16 rows of each plot were harvested with commercial equipment on September 23. Calculated weights of uncleaned seed (lbs. per acre) from each harvested area were: Carzol-Thiodan, 4-6 bugs/sweep, 1,230 lbs./A, Carzol-Thiodan 8-12 bugs/sweep, 1,044 lbs./A, Carzol-UniRoyal K840 8-12 bugs/sweep, 1,031 lbs./A.

The systemic insecticides, Temik and Shell SD8832 were applied as 10% granules to the soil at a rate of 3.0 lbs. AI/A. Three plots, each 2.37 acres were treated. The Temik granules were applied to two plots, one plot was treated on April 23, soon after the normal spring clipping of the alfalfa and the other on May 28, after much regrowth had occurred. The SD8832 plot was treated on April 23. The insecticides were applied with a six-row applicator with two shanks per row, 9 inches on each side of the plant row and approximately

6 inches deep. These plots did not receive any additional insecticide treatments. The remainder of the field, approximately 8 acres, received no insecticides during the season and served as a check. Lygus bug control was poor in this experiment. There was no evidence that the Temik and SD8832 applied on April 23 had any effect on lygus bug populations. Somewhat lower lygus bug populations occurred in the Temik plot that was treated on May 28, than in the check and in the other treatments, but the numbers were far above economic levels. It is difficult to draw conclusions from the data obtained because of some differences in quantities of irrigation water received by the plots during the season. Adult lygus bugs move from dry areas into green areas and some of the greenest occurred in the untreated check. Lygus bug populations peaked on July 23 in the treated plots and declined rapidly thereafter. Two high peaks occurred in the check, one on July 9 and the other on July 23. A third smaller peak occurred in the check on August 6. It was felt that the prolonged period of high populations in the check was due to the greener condition of plants in this area and the consequent attraction for migrating bugs and continued reproduction.

Although poor control occurred with the insecticides, much valuable information was obtained from the large untreated check, concerning lygus bug population trends and the populations of the entire complex of insects normally found in untreated alfalfa seed fields. This area will remain untreated for the next four years to permit a study of the insect complex in the absence of insecticides. It was obvious from the data obtained that the lygus bug populations reached an equilibrium with the environment, although, at high levels. The natural factors influencing lygus bug populations are not well understood. Several predatory species are known to feed upon lygus bug eggs and nymphs but their effects are largely unknown because they are drastically suppressed with heavy insecticide programs.

The very high populations of lygus bugs encountered in this study caused extreme damage to developing buds severely reducing seed production. At harvest the following net weights of uncleaned seed were obtained from each of the 2.37 acre areas. SD8832 416 lbs., Temik applied on April 23, 598 lbs., Temik applied on May 28, 838 lbs., check 714 lbs. The quantities of seed harvested are of significance only in that they were produced under adverse conditions. Most of the seeds produced were set prior

to the occurrence of the high lygus bug populations beginning early in June. It must be emphasized that seed production in this experiment was greatly influenced by irrigation practices mentioned earlier and the effects of the insecticides were actually of little consequence as far as seed yields are concerned.

Four samples of seed pods were hand stripped from plants in each plot prior to harvest. These were hand threshed and lightly cleaned in a Clipper seed cleaner. The seeds were then examined for lygus bug injury, seed chalcid, stink bug and other damage. The per cent of good seeds in the samples taken from the check was 76.0, from the SD8832 plot 79.8, and from the Temik treatments applied on April 23 and May 28, 79.8 and 92.1, respectively. The per cent of seeds damaged by lygus bugs in the respective treatments were check 10.1, SD8832 19.1, Temik 4/23, 16.8 and Temik 5/28, 5.3. Data pertaining to the quality of the seed may indicate some beneficial effect of the May 28 Temik treatment.

Aphids

Data on control of aphids were obtained for all materials evaluated for lygus bug control. Of the insecticides evaluated, the most effective in controlling the spotted alfalfa aphid were UniRoyal K840 and Lorsban. UniRoyal K840 was used at a rate of 0.5 lb. AI/A and was combined with Carzol 0.5 or 0.75 AI/A in all experiments. Outstanding control of the spotted alfalfa aphid was obtained in all experiments where UniRoyal K840 was used and aphid populations were held to low levels for periods of three weeks or more after application. The addition of a surfactant (Uni-1141A) to the Carzol-K840 combination did not appear to enhance aphid control.

Lorsban was evaluated at rates 0.5 and 1.0 lb. AI/A. It was used alone and in a combination of Carzol 0.5 + Lorsban 1.0 lb. AI/A. Lorsban did not appear to be as effective as UniRoyal K840 in controlling the spotted alfalfa aphid but results with Lorsban were excellent and aphid populations were held to very low levels for periods of up to 20 days after application. Data with this material are limited but there would seem to be little difference in the control obtained with the two rates of 0.5 and 1.0 lb. AI/A.

A combination of Lannate 0.75 + TEPP 1.0 lb. AI/A was also effective in controlling the spotted alfalfa aphid. Experience with this combination was limited to three trials involving plots previously treated with other matierals that had failed to control the spotted alfalfa aphid. The Lannate-

TEPP combination was effective in the three tests and held aphid populations to low levels for 13 days after application. It is conceivable that longer residual effects would have been noted had it been possible to prolong the experiments. The effectiveness of this combination is of interest because neither Lannate nor TEPP alone is effective in controlling the spotted alfalfa aphid. The combining of these materials may have produced a synergistic effect. Further studies will be conducted.

In an early experiment, in June, Bay Hox 1901 and dimethoate appeared to suppress the spotted alfalfa aphid. In this same experiment Monitor and Vydate at 0.5 and 0.75 lb. AI/A respectively, did not control the spotted alfalfa aphid and these materials appeared to have possibly stimulated the aphid populations. Spotted alfalfa aphid populations doubled during a six-day period where a second application of Monitor was made to a plot previously treated with this material. In a later experiment Vydate at 0.5 lb. AI/A did not control the spotted alfalfa aphid; a 75% increase in the population was noted 6 days after application and the population had increased 131 per cent 13 days after application. Combinations of Carzol with Thiodan, Lannate, TEPP and Vydate did not control the spotted alfalfa aphid. In the season-long treatment timing experiment for lygus bug control, mentioned earlier, it became necessary to substitute other treatments for the Carzol-Thiodan combination to prevent severe spotted alfalfa aphid damage from occurring.

It was not possible to evaluate the effectiveness of SD8832 and Temik applied to the soil as a control for the spotted alfalfa aphid. The alfalfa variety used in this experiment was resistant to the spotted alfalfa aphid.

The pea aphid was present in early April when the experiment was begun but the population declined rapidly in the untreated check as well as in the treated plots. There were no discernible differences between the treatments and the check.

Although UniRoyal K840 provided excellent control of the spotted alfalfa aphid, it appears that UniRoyal does not intend to proceed with further development of this material at the present time. Markets do not appear sufficient to justify expenditures for its development and manufacture. Research emphasis in 1975 will therefore be placed on Carzol-Lorsban combinations and combinations of Lannate-TEPP. New aphicides will be evaluated as they become available.

Spider Mites

The effects of insecticide applications on spider mite populations were evaluated in three experiments. The Carzol combinations all resulted in excellent control of spider mites. While some mites could be found in plots treated with Carzol the numbers were very low after treatment and they remained low for periods of up to 30 days after treatment. Repeated applications of Carzol in combination with Thiodan or UniRoyal K840 in the insecticide timing experiment for lygus bug control held mite populations to very low levels for the entire season. Bay Hox 1901, dimethoate, Monitor and Vydate as applied for lygus bug control, did not control spider mites. Heavy mite populations developed in plots treated with Monitor and with Vydate.

Lorsban did not appear to be highly effective in controlling spider mites but populations did not increase greatly where this material was used.

Spider mite populations were low until about August 6 in the experiment where SD8832 and Temik were applied to the soil. It would appear from the populations occurring in the check and treatments during August that the treatments may have reduced the mite populations. However, differences between the treatments are slight. The seasonal population curve for the untreated check shows the highest mite numbers occurring during the month of August with the population peak occurring on August 20.

Consperse stink bug

Stink bug populations were measured in six alfalfa seed fields on the west side of the San Joaquin Valley on three dates, May 14-18 , July 9-10 and September 4-24. In late September seven additional fields were surveyed bringing the total to 13. The stink bug populations were sampled by using the "beating pan" technique developed in 1971 where five pan samples (25 feet of row) were examined in each field on each sampling date. Extremely low populations were encountered in these fields. No stink bugs were found in any of the fields at the May sampling. A total of only 4 nymphs were found in July. In September, eight of the 13 fields had very small populations consisting mostly of nymphs.

Seed samples were hand harvested from each of the eight infested fields just prior to harvest. Seeds from these samples were examined for sucking insect damage and other injuries. Damage attributed to the stink

bug was in keeping with the low populations observed in the sampling areas and ranged from 0 to 2.2% averaging approximately 1.04%.

Because of the generally low stink bug populations in seed alfalfa fields, no experiments were conducted with insecticides for their control. The populations were not sufficiently high over large enough areas to permit adequate insecticide evaluations.

Effects of Insecticides on Beneficial Insect Species

In each of the lygus bug and aphid control experiments, data were obtained on the effects of the various insecticides on 9 groups of predatory or parasitic arthropods. Much data were gathered and it is difficult to generalize but it would appear that all of the treatments, with the exception of SD8832 and Temik applied to the soil, had drastic effects on populations of the predatory species. Orius, Nabis and spiders appeared to survive some of the treatments better than other predators but even these populations were severely reduced. In the season-long insecticide timing experiment for lygus bug control, repeated applications of Carzol + Thiodan and applications of TEPP, Lorsban and Lannate + TEPP virtually eliminated the spiders as well as the other beneficial species.

One of the purposes of the large untreated check area associated with the Temik and SD8832 experiment was to study populations of predatory arthropods in the absence of insecticides. The species were sampled with a D-Vac suction machine at weekly intervals from April 2 to September 24. Following harvest in late September, sampling was resumed and is continuing at bi-weekly intervals throughout the winter. The collections are placed in Berlese separatory funnels to remove the insects from plant debris taken in the samples. The insects are then counted and recorded. The following groups of insects are recorded as to numbers of adults and larvae or nymphs: Orius (miute pirate bugs), Geocoris (big eyed bugs), Nabis (damsel bugs), lacewings, syrphid flies, coccinellid beetles (lady beetles), collops beetles, spiders and parasitic wasps. The populations of each group occurring through September 24 are shown in tables and graphs accompanying this report.

Predators occurring in the largest numbers throughout the period were Orius, Nabis, and spiders.

Small Hymenoptera (wasps), many of which are believed to be parasitic, were also present in fairly high numbers. The minute pirate bug, Orius, was abundant from June 11 through July 23. The population of Orius reached a peak on July 9 with smaller peaks on June 11 and July 23. Nabis was present in moderate numbers from June 11 through August 6. Peak numbers of Nabis occurred on June 11 and July 9. Geocoris was present in relatively small numbers throughout the season. The peak population of Geocoris occurred on September 11 with smaller peaks on July 9, August 6 and August 27. The spider population was greatest on July 23 with smaller peaks occurring on July 9, August 6 and September 11.

Lacewings, syrphid flies, lady beetles and Collops beetles were almost totally absent. These insects prey on aphids and the aphid populations were extremely low owing to the fact that the alfalfa variety was aphid resistant.

It is significant to note that although insecticides were not applied to the check area the predators were unable to effectively cope with the lygus bug populations. It will be of interest to determine if predator populations will increase sufficiently in subsequent years, in the absence of insecticides, to reduce lygus bug populations.

epp	1.0								

[1] Plot size: 10 acres (330' x 1320').

[2] Applications were made by aircraft at 10 GPA. Two additional treatments (*) were required to control high populations of the spotted alfalfa aphid; Tepp at 1.0 lb. per acre was used on July 24 and Lorsban at 0.5 and 1.0 lb. per acre (5 acres each) was used on August 7. The Lorsban treatment may have extended the time before the next required lygus bug treatment.

[3] Pretreatment counts were made on June 11.

[4] Average of 20 sweeps on each sampling date.

Lygus bug populations in a seed alfalfa plot where insecticides were applied at counts of 8 to 12 lygus bugs per sweep. John Maitia, Firebaugh, California, 1974.

1/ Insecticide applications -

K - Applied at lygus bug counts of 4 to 6 per sweep as follows: Carzol 0.5 plus Thiodan 1.0 lb. AI per acre on June 12, July 10 and July 31. Lannate 0.75 plus Tepp 1.0 AI per acre on August 28. Two additional treatments were required to control high populations of spotted alfalfa aphid, Tepp 1.0 lb. AI per acre on July 24 and Lorsban 0.5 and 1.0 lb. per acre (5 acres each) on August 7. Plot size 10 acres.

L - Applied at lygus bug counts of 8 to 12 per sweep as follows: Carzol 0.5 plus Thiodan 1.0 lb. AI per acre on June 12 and July 17, Lannate 0.75 plus Tepp 1.0 lb. AI per acre on August 21. Two additional treatments were required to control high populations of spotted alfalfa aphid, Tepp 1.0 AI per acre on July 24 and Lannate 0.75 plus Tepp 1.0 lb. per acre on August 7. Plot size 10 acres.

M - Applied at lygus bug counts of 8 to 12 per sweep as follows: Carzol 0.5 plus UniRoyal K840 0.5 lb. AI per acre on June 12 and Carzol 0.75 plus UniRoyal K840 0.5 Lb. AI per acre on July 3 and August 7. Plot size 5 acres.

2/ Four samples of pods, approximately 1 quart each, were hand stripped from plants in each plot prior to commercial harvest. Samples were hand threshed and lightly cleaned in a clipper seed cleaner. Counts based on 4 subsamples from each of the threshed samples.

Note: The center 16 rows of each plot were harvested with commercial equipment on September 23. Calculated weights of seed (lbs. per acre) from each harvested area were:

	Uncleaned seed	Cleaned seed
K	1,230	1,160
L	1,044	973
M	1,031	949

1/ Plot size: Each treatment 2.37 acres (253' x 408'). Granular insecticides were applied at 3.0 lb. AI per acre with a 6-row commercial applicator, SD 8832 and Temik on April 23 and Temik on May 28. Plots were irrigated April 27-30 and again May 30-June 2.

2/ Four samples of pods from each plot were hand stripped from plants prior to commercial harvest. Samples were hand threshed and lightly cleaned in a clipper seed cleaner. Counts based on 4 subsamples from each of the threshed samples.

1/ Plot size: Each treatment 5 acres (165' x 1320').

2/ Sprays were applied at 10 GPA. Carzol was a 92% soluble powder while others were emulsifiable concentrates. All plots were treated August 14 from 4:55 to 5:50 A.M.

3/ Pretreatment counts were made August 13.

4/ 2-25 suck D-Vac samples were taken in each plot on each sampling date.

Predator and parasite populations in a seed alfalfa plot where insecticides were applied at counts of 4 to 6 lygus bugs per sweep. John Maitia, Firebaugh, California, 1974.
